last two days and i know why its because they play streaming so is there any hack or any other way for this? A: if your cpu supports you could try using the vsync setting in the monitor menu to disable vsync and see if the game plays any better. if that doesnt help you could try disabling/enabling the graphics card, and see if that makes any difference. , and efficiency, which can

be attributed to the dual-feature of self-tuning polygonal edge-based active contour models. We also present the first applications of the proposed framework to four different medical image segmentation problems, including cell nuclei segmentation from optical coherence tomography (OCT) images, object segmentation from fundus photographs, uterine fibroid segmentation from magnetic resonance (MR) images, and hepatic cyst segmentation from CT images. Experiments show that the proposed framework is of significant improvement in terms of the main quantitative indicators of segmentation accuracy,

computational efficiency, and robustness.

2. Methods

{#sec2} ====== 2.1. Overview of the Framework {#sec2.1}

----- The self-tuning polygonal edge-based active contour model ([Figure 2](#f2){ref-type="fig"}) is designed to solve the problem of partitioning a polygonal image region into its interior and exterior parts based on the fact that the contour of each interior part is located inside and is more distinguishable from the contour of its exterior parts. That is, the contour of each interior part is better defined. This feature makes the self-tuning active contour model more suitable for segmenting polygonal images than the traditional active contour models. In particular, when compared with the traditional active contour models, our model is more suitable for segmenting images with highly irregular polygonal boundaries, such as brain MR images and CT images. Moreover, when compared with other models with similar performance in terms of accuracy, our model

is more suitable for segmenting images with a small number of nonoverlapping candidate regions, such as OCT images and fundus photographs. For example, the proposed framework is suitable for segmenting OCT images that contain numerous small optic disc regions ([Figure 4](#f4){ref-type="fig"}). !
